XXXII. NWA3171
Basaltic Shergottite
506 grams

Figure XXXII-1: Complete NWA3171 stone showing flow lines in the back fusion crust on the shield-like front face. Photo by David Gregory.

**Introduction**

NWA 3171 is a 506 gram stone, partially broken, partially covered with fresh fusion crust (figure XXXII-1). It was purchased in 2004 by A.A. Aaronson for D.A. Gregory and is apparently from western Algeria. It is apparently very similar to Shergotty and Zagami.

Thin veins of black glass leading to shock melt pockets can be seen in photos of the sawn surface (figure XXXII-2).

**Petrography**

This Martian basalt consists of approximately equal amounts of pyroxene and plagioclase (figure XXXII-3). Accessory phases include ulvospinel, ilmenite, chlorapatite, merrillite, pyrrhotite, Na-K-Al-Si glass, silica, and rare baddeleyite. Rare calcite, barite and minor rust staining are also present in this dessert find (Irving et al. 2004).

Additional petrographic detail and figures can be found at [http://www2.jpl.nasa.gov/snc/nwa3171.html](http://www2.jpl.nasa.gov/snc/nwa3171.html).

**Mineralogy**

**Pyroxene:** The composition of pyroxene in NWA3171 is given in figure XXXII-4 (Irving et al. 2004).

**Plagioclase:** The plagioclase is shocked to maskelynite (An$_{41-54}$).

**Chemistry**

None

**Radiogenic age dating**

None

**Other Studies**

Oxygen isotopes for NWA3171 are $\delta^{18}O = 4.56 \pm 0.1$, $\delta^{17}O = 2.77 \pm 0.1$ and $\delta^{17}O = 0.40 \pm 0.06$ ‰ (as determined by T. Larson and F. Longstaffe, Univ. Western Ontario).
