

INTRODUCTION: 65735 is a light gray, friable breccia collected as a rake sample (Fig. 1). Clasts of gray, crystalline rock (~1 mm), white, anorthositic material (~1 mm) and rare fragments of a yellow mafic(?) silicate (up to 3 mm) are present. It is subangular with few zap pits.

PROCESSING AND SUBDIVISIONS: During initial processing and macroscopic examination in 1972, this rock fell into two subequal pieces (Fig. 1). Both are grouped as 65735,0.

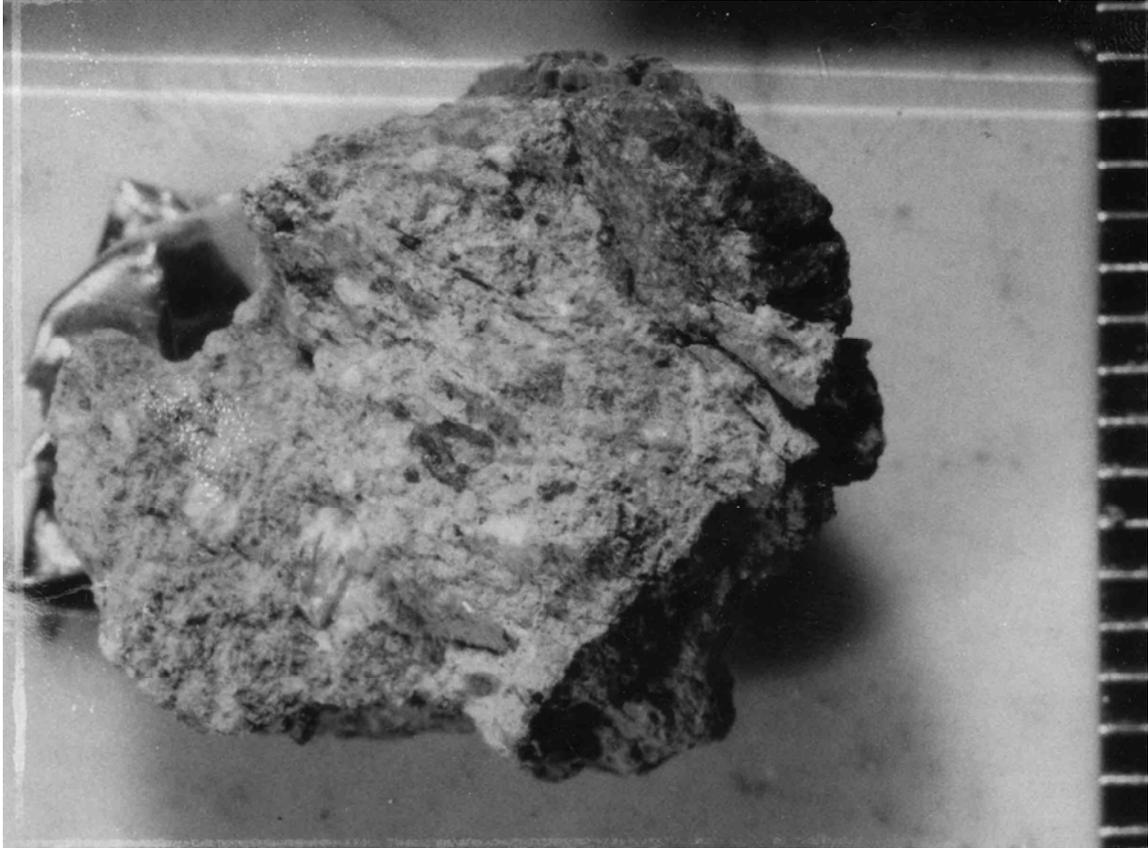

FIGURE 1. Smallest scale division in mm. Photos are of two separate pieces.
