

INTRODUCTION: 67696 is a coherent, black, vesicular glass with a smooth exterior surface and broken elsewhere (Fig. 1). The glass encloses white clasts (or coated a white rock) and is at least partly crystallized into plagioclase laths. The vesicles include some more than a centimeter across. It is a rake sample collected 30 m east of the White Breccia boulders and appears to lack zap pits.

PROCESSING AND SUBDIVISIONS: 67696 was originally the second largest of four fragments numbered together as 67629, now renumbered 67629, 67695, 67696, and 67697.
